

# Mutation

**David E. Culler**

**CS8 – Computational Structures in Data Science**

<http://inst.eecs.berkeley.edu/~cs88>

**Lecture 8**

October 15, 2018

# Computational Concepts Toolbox

---

- Data type: values, literals, operations,
- Expressions, Call expression
- Variables
- Assignment Statement
- Sequences: tuple, list
- **Dictionaries**
- Data structures
- Tuple assignment
- Function Definition Statement
- Conditional Statement
- Iteration: list comp, for, while
- **Lambda function expr.**
- Higher Order Functions
  - Functions as Values
  - Functions with functions as argument
  - Assignment of function values
- Higher order function patterns
  - Map, Filter, Reduce
- Function factories – create and return functions
- Recursion
  - Linear, Tail, Tree
- **Abstract Data Types**

# C.O.R.E concepts

## Compute

Perform useful computations treating objects abstractly as whole values and operating on them.

## Operations

Provide operations on the abstract components that allow ease of use – independent of concrete representation.

## Representation

Constructors and selectors that provide an abstract interface to a concrete representation

## Evaluation

Execution on a computing machine

Abstract Data Type

Abstraction Barrier

# Creating an Abstract Data Type

---

- **Operations**
  - Express the behavior of objects, invariants, etc
  - Implemented (abstractly) in terms of Constructors and Selectors for the object
- **Representation**
  - Constructors & Selectors
  - Implement the structure of the object
- **An *abstraction barrier violation* occurs when a part of the program that can use the higher level functions uses lower level ones instead**
  - At either layer of abstraction
- **Abstraction barriers make programs easier to get right, maintain, and modify**
  - Few changes when representation changes

# Review: Dictionaries – by example

---

- **Constructors :**

- `dict( hi=32, lo=17)`
- `dict([('hi',212), ('lo',32), (17,3)])`
- `{'x':1, 'y':2, 3:4}`
- `{wd:len(wd) for wd in "The quick brown fox".split() }`

- **Selectors :**

- `water['lo']`
- `<dict>.keys(), .items(), .values()`
- `<dict>.get(key [, default] )`

- **Operations :**

- `in, not in, len, min, max`
- `'lo' in water`

- **Mutators**

- `water[ 'lo' ] = 33`

# Objects

---

- **Objects represent information**
- **Consist of data and behavior, bundled together to create abstractions**
  - Abstract Data Types
- **They can have state**
  - mutable vs immutable
- **Object-oriented programming**
  - A methodology for organizing large programs
  - So important it is supported in the language (classes)
- **In Python, every value is an object**
  - All **objects** have **attributes**
  - Manipulation happens through **methods**
- **Functions do one thing (well)**
  - Object do a collection of related things

# Mutability

---

- **Immutable** – the value of the object cannot be changed
  - integers, floats, booleans
  - strings, tuples
- **Mutable** – the value of the object can ...
  - Lists
  - Dictionaries

```
>>> alist = [1,2,3,4]
>>> alist
[1, 2, 3, 4]
>>> alist[2]
3
>>> alist[2] = 'elephant'
>>> alist
[1, 2, 'elephant', 4]
```

```
>>> adict = {'a':1, 'b':2}
>>> adict
{'b': 2, 'a': 1}
>>> adict['b']
2
>>> adict['b'] = 42
>>> adict['c'] = 'elephant'
>>> adict
{'b': 42, 'c': 'elephant', 'a': 1}
```

# Are these 'mutation' ?

---

```
def sum(seq):  
    psum = 0  
    for x in seq:  
        psum = psum + x  
    return psum
```

```
def reverse(seq):  
    rev = []  
    for x in seq:  
        rev = [x] + rev  
    return rev
```

# From value to storage ...

- A variable assigned a compound value (object) is a *reference* to that object.
- Mutable object can be changed but the variable(s) still refer to it

```
x = [1, 2, 3]
y = 6
x[1] = y
x[1]
```

# Mutation makes sharing visible

Python 3.6

```
1 x = 2
2 y = 3
3 print(x+y)
4 x = 4
→ 5 print(x+y)
```

[Edit this code](#)

Print output (drag lower right corner to resize)

```

list

0	1
1	3

# Sharing

# Copies, 'is' and '=='

---

```
>>> alist = [1, 2, 3, 4]
>>> alist == [1, 2, 3, 4] # Equal values?
True
>>> alist is [1, 2, 3, 4] # same object?
False
>>> blist = alist # assignment refers
>>> alist is blist # to same object
True
>>> blist = list(alist) # type constructors copy
>>> blist is alist
False
>>> blist = alist[ : ] # so does slicing
>>> blist is alist
False
>>> blist
[1, 2, 3, 4]
>>>
```

# Creating mutating ‘functions’

---

- Pure functions have *referential transparency*
- Result value depends only on the inputs
  - Same inputs, same result value
- Functions that use global variables are not pure
- Higher order function returns embody state
- They can be “mutating”

```
>>> counter = -1
>>> def count_fun():
...     global counter
...     counter += 1
...     return counter
...
>>> count_fun()
0
>>> count_fun()
1
```

# Creating mutating 'functions'

```
>>> counter = -1
>>> def count_fun():
...     global counter
...     counter += 1
...     return counter
...
>>> count_fun()
0
>>> count_fun()
1
```

How do I make a second counter?

```
>>> def make_counter():
...     counter = -1
...     def counts():
...         nonlocal counter
...         counter += 1
...         return counter
...     return counts
...
>>> count_fun = make_counter()
>>> count_fun()
0
>>> count_fun()
1
>>> nother_one = make_counter()
>>> nother_one()
0
>>> count_fun()
2
```

# Creating mutable objects

---

- Follow the ADT methodology, enclosing state within the abstraction

# Useless bank account

---

```
def account(name, initial_deposit):  
    return (name, initial_deposit)  
  
def account_name(acct):  
    return acct[0]  
  
def account_balance(acct):  
    return acct[1]  
  
def deposit(acct, amount):  
    return (acct[0], acct[1]+amount)  
  
def withdraw(acct, amount):  
    return (acct[0], acct[1]-amount)
```

```
>>> my_acct = account('David Culler', 175)  
>>> my_acct  
( 'David Culler', 175)  
>>> deposit(my_acct, 35)  
( 'David Culler', 210)  
>>> account_balance(my_acct)  
175
```

# Bank account using dict

```
def account(name, initial_deposit):  
    return {'Name' : name, 'Number': 0,  
           'Balance' : initial_deposit}  
  
def account_name(acct):  
    return acct['Name']  
  
def account_balance(acct):  
    return acct['Balance']  
  
def deposit(acct, amount):  
    acct['Balance'] += amount  
    return acct['Balance']  
  
def withdraw(acct, amount):  
    acct['Balance'] -= amount  
    return acct['Balance']
```

```
>>> my_acct = account('David Culler', 93)  
>>> account_balance(my_acct)  
93  
>>> deposit(my_acct, 100)  
193  
>>> account_balance(my_acct)  
193  
>>> withdraw(my_acct, 10)  
183  
>>> account_balance(my_acct)  
183  
>>> your_acct = account("Fred Jones", 0)  
>>> deposit(your_acct, 75)  
75  
>>> account_balance(my_acct)  
183
```

# State for a class of objects

```
account_number_seed = 1000

def account(name, initial_deposit):
