Computational Structures in Data Science

Object-Oriented Programming: Part 2, Inheritence

Announcements

- Midterm 10/ 7-9pm
  - Locations and assignments will be sent early next week
  - Unli19mited Handwritten Sheets – but try to use no more than 3-4!
- Lecture: Thurs 10/14 – More OOP Practice
- Lecture: Tues 10/18 – Exam Review / Q&A
- Check the Calendar!
  - Exam Review Sessions led by Tutors Fri 3-5pm (Cory 277) (time moved!)
  - New "topical" review sessions by TAs
  - CSM review sessions too
- No labs next week
- TAKE A DEEP BREATH! Y'all can do this. ☺

Classes Can Have Attributes Too!

- Class attributes (as opposed to *instance* attributes) belong to the class itself, instead of each object
  - This means there is one value which is shared for all of the class's objects
- Be Careful!
  - It's easy to overdo class attributes

Example: class attribute

```
class BaseAccount:
    account_number_seed = 1000

    def __init__(self, name, initial_deposit):
        self._name = name
        self._balance = initial_deposit
        self._acct_no = BaseAccount.account_number_seed
        BaseAccount.account_number_seed += 1

    def name(self):
        return self._name

    def balance(self):
        return self._balance

    def withdraw(self, amount):
        self._balance -= amount
        return self._balance
```

More class attributes

```
class BaseAccount:
    account_number_seed = 1000
    accounts = []
    def __init__(self, name, initial_deposit):
        self._name = name
        self._balance = initial_deposit
        self._acct_no = BaseAccount.account_number_seed
        BaseAccount.account_number_seed += 1
        BaseAccount.accounts.append(self)

    def name(self):
        ...

    def show_accounts():
        for account in BaseAccount.accounts:
            print(account.name(),
                  account.account_no(),account.balance())
```

Object-Oriented Programming: "Magic" Methods

Learning Objectives

- Python's Special Methods define built-in properties
  - `__init__ # Called when making a new instance`
  - `__sub__ # Maps to the - operator`
  - `__str__ # Called when we call print()`
  - `__repr__ # Called in the interpreter`

Special Initialization Method

`__init__` is called automatically when we write:

```
my_account = BaseAccount('me', 0)
```

```
class BaseAccount:

    def __init__(self, name, initial_deposit):
        self.name = name
        self.balance = initial_deposit

    def account_name(self):
        return self.name

    def account_balance(self):
        return self.balance

    def withdraw(self, amount):
        self.balance -= amount
        return self.balance
```

return None

More special methods

```
class BaseAccount:
        … (init, etc removed)
    def deposit(self, amount):
        self._balance += amount
        return self._balance

    def __repr__(self):
        return '< ' + str(self._acct_no) +
               '[' + str(self._name) + '] >'

    def __str__(self):
        return 'Account: ' + str(self._acct_no) +
               '[' + str(self._name) + ']'

    def show_accounts():
        for account in BaseAccount.accounts:
            print(account)
```

Goal: unambiguous

Goal: readable

More Magic Methods

- We will **not** go through an exhaustive list!
- Magic Methods start and end with "double underscores" `__`
- They map to built-in functionality in Python. Many are logical names:
  - `__add__` => `+` operator
  - `__sub__` => `-` operator
  - `__getitem__` => `[]` operator
- A longer list for the curious:
  - https://docs.python.org/3/reference/datamodel.html

Object-Oriented Programming: Inheritance

Learning Objectives

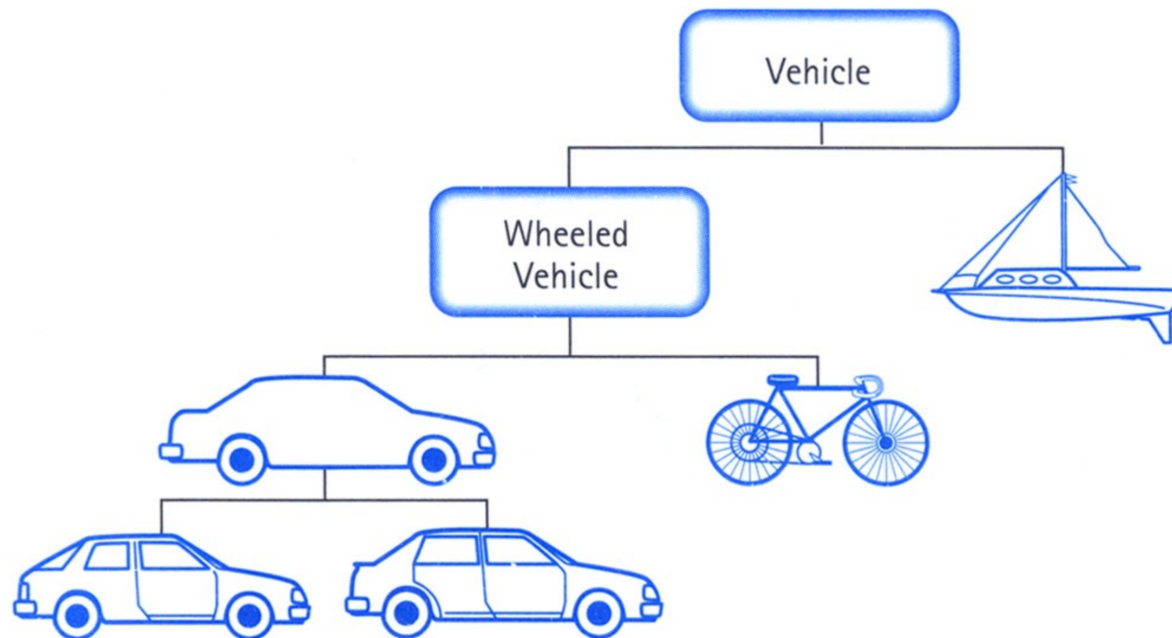
- Inheritance allows classes to reuse methods and attributes from a parent class.
- super() is a new method in Python
- Subclasses or child classes are distinct from on another, but share properties of the parent.

Inheritance

- Define a class as a specialization of an existing class
- Inherent its attributes, methods (behaviors)
- Add additional ones
- Redefine (specialize) existing ones
  - Ones in superclass still accessible in its namespace

Class Inheritance

- Classes can inherit methods and attributes from parent classes but extend into their own class.



Python class statement

```
class ClassName:
    <statement-1>
    .
    .
    .
    <statement-N>
```

```
class ClassName ( inherits / parent-class ):
    <statement-1>
    .
    .
    .
    <statement-N>
```

Example

```
class Account:
    def __init__(self, name, initial_deposit):
        # Initialize the instance attributes
        self._name = name
        self._acct_no = Account._account_number_seed
        Account._account_number_seed += 1
        self._balance = initial_deposit

class CheckingAccount(Account):
    def __init__(self, name, initial_deposit):
        # Use superclass initializer
        Account.__init__(self, name, initial_deposit)
        # Alternatively:
        # super().__init__(name, initial_deposit)
        # Additional initialization
        self._type = "Checking"
```

Accessing the Parent Class

- `super()` gives us access to methods in the parent or "superclass"
  - Can be called anywhere in our class
  - Handles passing `self` to the method
- We can directly call `ParentClass.method(self, …)`
  - This is not quite as flexible if our class structure changes.
