Higher Order Functions

A **higher order function** (HOF) is a function that manipulates other functions by taking in functions as arguments, returning a function, or both.

1.1 Functions as Arguments

One way a higher order function can exploit other functions is by taking functions as input. Consider this higher order function called negate.

```
def negate(f, x):
    return -f(x)
```

negate takes in a function f and a number x. It doesn't care what exactly f does, as long as f takes in a number and returns a number. Its job is simple: call f on x and return the negation of that value.

1.2 Questions

1. Here are some possible functions that can be passed through as f.

```
def square(n):
    return n * n

def double(n):
    return 2 * n

What will the following Python statements output?
>>> negate(square, 5)

>>> negate(double, -19)

>>> negate(double, negate(square, -4))
```

2. Implement a function keep_ints, which takes in a function cond and a number n, and only prints a number from 1 to n if calling cond on that number returns True:

```
def keep_ints(cond, n):
    """Print out all integers 1..i..n where cond(i) is true

>>> def is_even(x):
    ...  # Even numbers have remainder 0 when divided by 2.
    ...  return x % 2 == 0
>>> keep_ints(is_even, 5)
2
4
"""
```

1.3 Functions as Return Values

Often, we will need to write a function that returns another function. One way to do this is to define a function inside of a function:

```
def outer(x):
    def inner(y):
        ...
    return inner
```

The return value of outer is the function inner. This is a case of a function returning a function. In this example, inner is defined inside of outer. Although this is a common pattern, we can also define inner outside of outer and still use the same return statement.

```
def inner(y):
    ...
def outer(x):
    return inner
```

1.4 Questions

1. Use this definition of outer to fill in what Python would print when the following lines are evaluated.

```
def outer(n):
    def inner(m):
        return n - m
    return inner
>>> outer(61)

>>> f = outer(10)
>>> f(4)

>>> outer(5)(4)
```

2. Implement a function keep_ints like before, but now it takes in a number n and returns a function that has one parameter cond. The returned function prints out all numbers from 1..i..n where calling cond(i) returns True.

```
def keep_ints(n):
    """Returns a function which takes one parameter cond and
    prints out all integers 1..i..n where calling cond(i)
    returns True.

>>> def is_even(x):
    ... # Even numbers have remainder 0 when divided by 2.
    ... return x % 2 == 0
    >>> keep_ints(5)(is_even)
    2
    4
    """
```

2 Environment

3 Questions

1. Draw the environment diagram for evaluating the following code

2. Draw the environment diagram for evaluating the following code

3. Draw the environment diagram for evaluating the following code

4. Draw the environment diagram for evaluating the following code
 def spain(japan, iran):
 def world(cup, egypt):
 return japan-poland
 return iran(world(iran, poland))

def saudi(arabia):
 return japan + 3

japan, poland = 3, 7
 spain(poland+1, saudi)

5. Draw the environment diagram for evaluating the following code

```
cap = 9
hulk = 3

def marvel(cap, thor, avengers):
    marvel = avengers
    iron = hulk + cap
    if thor > cap:
        def marvel(cap, thor, avengers):
            return iron
    else:
        iron = hulk
    return marvel(thor, cap, marvel)

def iron(man):
    hulk = cap - 1
    return hulk

marvel(cap, iron(3), marvel)
```
